Appendix A | Methodology

This section discusses the methodology used for measuring level of service (LOS) in the current monitoring cycle. In the first step, days within the monitoring period of September to early November 2020 were screened to ensure that automatically collected data used was only for days that were expected to result in normal commuter traffic conditions. Days that may have produced lighter than usual traffic conditions (such as public holidays) or heavier than usual conditions (such as special events) were identified and removed. Similarly, field data collection days were identified based on local events and school holidays to ensure representative travel conditions.

The second step consisted of the actual data collection using either probe-vehicle based commercial speed data (e.g., INRIX data), freeway express lanes Electronic Toll System (ETS) data, or floating car survey data. Data was collected for the CMP freeway, HOV and express lanes, and arterial network.

In the final step, data was analyzed separately for commercial speed data, ETS data, and floating car surveys to assign LOS based on Highway Capacity Manual (HCM) methodologies.

A.1 | Screening for Data Collection Periods

As a preliminary step in the analysis, it was necessary to identify all the days and time periods during which the CMP network could be monitored. Again, travel time data was collected using a combination of commercial speed data and floating car surveys. Monitoring days for both data sources were reviewed and identified separately.

As a part of the preliminary analysis, all potential factors that may affect average traffic speeds were carefully examined. School holidays and special events that occurred during the monitoring period were identified and removed. This analysis was necessary to identify data generally representative of normal conditions on the CMP network for the current monitoring cycle.

A.1.1 | LOS Monitoring Times

LOS monitoring data was collected in fall 2020, not spring due to COVID-19, when schools were in session. Commercial speed data collection and floating car surveys were conducted in the months of September, October and November, 2020.

Weekday data was collected on Tuesdays, Wednesdays and Thursdays between September 1 and November 6, 2020 for the morning and afternoon peak-periods. The morning peak-period was from 7:00 AM to 9:00 AM, and the afternoon peak-period was from 4:00 PM to 6:00 PM. Freeways were also monitored separately on weekends between 1:00 PM to 3:00 PM, which were verified in earlier monitoring cycles to be the weekend peak-period.

All potential factors that may adversely impact traffic conditions were examined so monitoring results are an accurate reflection of the average driving conditions experienced by daily commuters. The following sections describe each of these screening steps in more detail.

A.1.2 | Public Holidays

Roads are typically less congested on public holidays which are therefore need to be excluded. Public holidays were reviewed and none occurred on Tuesdays, Wednesdays and Thursdays within the monitoring period in 2020.

A.1.3 | Special Events

Special events typically produce more congestion, especially on roadways near the event area, thus traffic data associated with special events was removed from the dataset. Due to COVID-19, no special events occurred within the monitoring period.

A.1.4 | Weather Events

Weather events were also considered as a part of the analysis; however, no events were observed to impact traffic conditions.

A.1.5 | Construction and Maintenance

The project team reviewed various information sources to identify significant construction impacts during the monitoring period. These included the following:

- Alameda CTC projects webpage;
- Other government websites (including Caltrans District 4);
- Specific construction project websites;
- Facebook and Twitter feeds (such as the 511 SF Bay Twitter Feed¹); and
- Caltrans Performance Measurement System (PeMS) lane closure database.

Construction and maintenance were reviewed and if significant impacts were identified, then data were removed across all relevant CMP segments.

A.1.6 | Incidents

Incidents (collisions, broken down vehicles, etc.) negatively impact traffic conditions, and therefore data associated with those incidents was excluded. For floating car surveys, where the driver observed an incident, the floating car survey run was repeated. For commercial speed data, freeway incident data sets from the Performance Monitoring System (PeMS) were reviewed and the speed data records for the time period corresponding to an incident were removed across all relevant CMP segments.

A.2 | Data Collection

Both probe vehicle-based commercial speed data and floating car survey data were used to measure average speed to determine the LOS.

A.2.1 | Commercial Speed Data

In 2013, MTC contracted with a third-party commercial data vendor, INRIX, to obtain region-wide commercial speed data, and has made the data available free of charge to CMAs and other local governments for planning and monitoring purposes. This LOS Monitoring effort used the commercial speed data from INRIX through MTC's contract.

¹ Twitter Feed for 511 SF Bay twitter.com/511SFBay

APPENDIX A

INRIX "aggregates traffic data from GPS-enabled vehicles and mobile devices, traditional road sensors and hundreds of other sources."² Traffic data is reported by INRIX using discrete roadway links defined as INRIX XD segments. INRIX XD are segments that cover more miles of road than Traffic Message Channels (TMC) segments, generally with greater granularity, and with the ability to adapt more quickly to changes in the road network and the addition of new roads and new markets. During the May-June 2019 timeframe, MTC switched from providing TMC-based data, used in the last several monitoring cycles, to XD-based data, which provides greater spatial resolution. However, TMC and XD datasets are two slightly different roadway segmentation systems. In this regard, it is worth noting the following advantages in general:

- XD links are contiguous along corridors whereas the TMC segments had occasional gaps between segments and occasional segment overlaps.
- On arterial roadways (non-freeway segments) the XD links beginning and ending points are aligned with roadway intersections whereas the TMC segments many times ended mid-block.
- The TMC segments were relatively long in rural or non-urbanized areas. The XD links are all generally less than a mile or so in length.

INRIX reports travel speeds on pre-determined XD segments. In 2020 monitoring, it was decided to switch from one-minute raw data to five-minute granularity, given that the latter is deemed of high quality without data gaps and aggregating five-minute data onto CMP segments will run more efficiently and accurately. The average vehicular speed reported for each five-minute period on each XD link culminates in millions of lines of data for a three-month county-wide dataset.

A.2.2 | Floating Car Survey Data

Where commercial speed data lacked either spatial or temporal coverage, floating car surveys were used. The floating car surveys were completed using GPS technology to determine the travel time between the start and end of each CMP segment. For each of these CMP segments on the arterials (Tier 1) and HOV/express lanes, the study completed six (6) floating car surveys. Floating car runs were completed using the industry accepted approach of attempting to represent the average vehicle. Drivers aimed to pass as many vehicles as passed them. Six (6) surveys were conducted in each of the morning (7 a.m. to 9 a.m.) and afternoon (4 p.m. to 6 p.m.) peak periods. Surveys were only undertaken on Tuesdays, Wednesdays, and/or Thursdays. For a particular segment, the surveys were scheduled so they spanned a range of days and times. The aim of this is to ensure that a range of representative traffic conditions are surveyed.

Drivers were instructed to comply with all road rules. This includes the speed limit, traffic signal displays and not stopping within intersections. In this respect, it is noted that there may be some minor differences between the results from these professional floating car surveys and normal driving behavior; however, these differences are unavoidable.

Several freeway ramps, which were not covered by commercial data, were also measured using floating car survey. If a CMP segment that used floating car surveys experienced congestion (LOS F) in the afternoon peak and the segment was subject to CMP conformity, then two additional runs were generally completed.

² INRIX. <http://inrix.com>

A.3 | Data Analysis

The methodology for deriving LOS from raw commercial speed and floating car survey data includes two key steps. The first step consists of converting the raw speed data into average peak-period speeds on every CMP segment. In the second step, average speeds are converted to estimate LOS using a specific method depending on the type and classification of roadway.

A.3.1 | Calculate Average Peak-Period Speed

The steps for converting raw speed data to average peak-period speeds vary based on the data source.

Commercial Speed Data

Once collected from the INRIX database, commercial speed data points were associated with the appropriate CMP segment through a spatial mapping process. Next, data outside the monitoring period and data with poor data quality were eliminated. To calculate average speed for all data points, the data was averaged on each CMP segment for each peak-period.

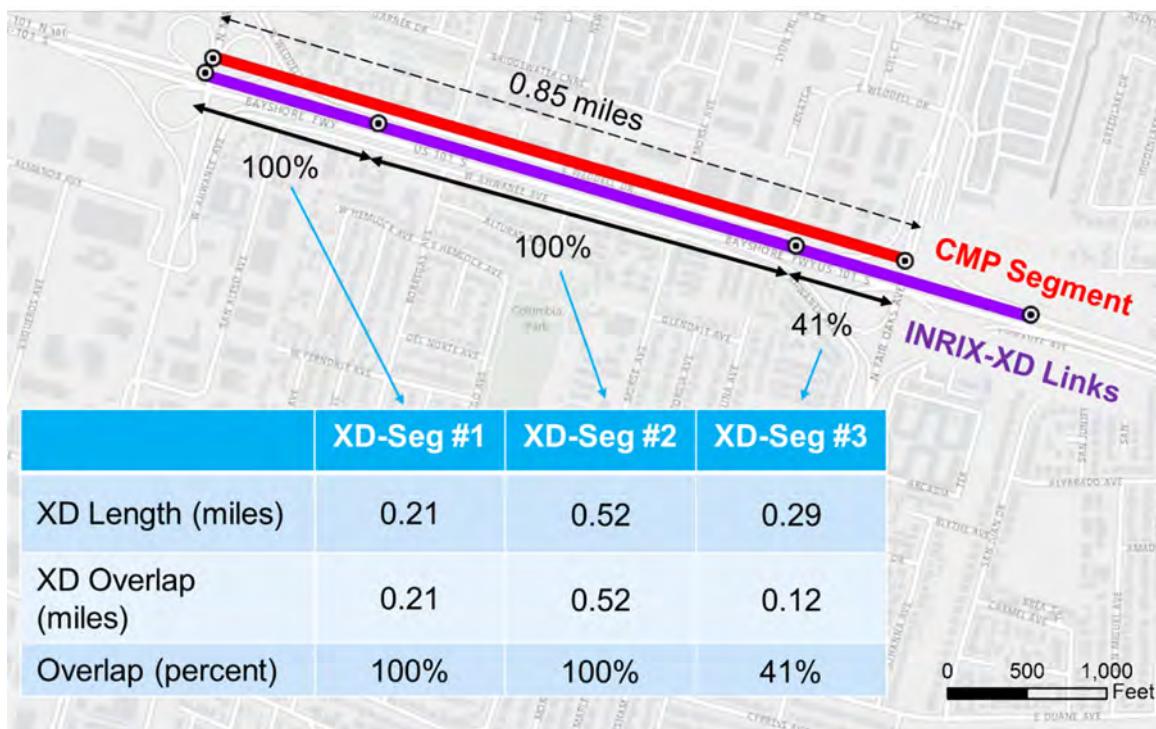

Step 1. Mapping INRIX XD links onto CMP Segments

Commercial speed data collected by INRIX was reported against lengths of roadway called INRIX XD links. For this project, it was required that the average speed be reported against an Alameda CTC CMP segment. CMP segments are typically longer sections of roadway, averaging approximately 1.2 mile in length (range: 0.2 to 5.0 miles). Therefore, INRIX XD links needed to be aligned against or mapped onto the CMP segments.

It should be noted that for some CMP segments, the ends of the CMP did not align with the ends of the INRIX XD segments. **Figure A-1** shows a schematic example to explain this concept. It shows one CMP segment that is made up of three INRIX XD segments. However, the end of the last INRIX XD segment does not align with the end of the CMP segment. In these instances, only the overlapping portion of the XD length was used to calculate the average speed.

APPENDIX A

Figure A-1: End points of CMP and INRIX XD do not align

Step 2. Filter Raw Data

The raw INRIX data was filtered to remove:

- Times outside the morning and afternoon peak periods;
- Days other than Tuesdays to Thursdays;
- Data points impacted by special events (e.g., incidents, construction, major events); and
- Data points with lower data quality scores.

INRIX includes a data quality score that accompanies every INRIX data point. The score value is defined as:

- Score of 30: Data are exclusively generated from real-time sources.
- Score of 20: A mix of historical and real-time sources are used.
- Score of 10: Data are exclusively generated from historical data.

Only raw speeds that were directly measured were used for computing LOS in the CMP network. As such, data points with scores of 10 and 20 were removed, and only data with scores of 30 (equivalent to 100% observed) were kept, as illustrated in **Figure A-2**.

The quantity of remaining data points was tracked so the sample size of score 30 was known. The sample sizes are presented in conjunction with all associated commercial speed data results.

Figure A-2: Example of Filtering Process

CMP					
XD					
Time Period	XD1	XD2	XD3	XD4	Length
1	20	30	30	30	3/4
2	20	30	30	30	3/4
3	30	30	30	30	1
4	30	30	30	30	1
5	30	30	30	30	1
6	20	30	20	30	1/2
7	30	30	20	30	3/4

Step 3. Spatial and Temporal Data Aggregation - Average Speed Computations

This step covers the methodology of aggregating the data, both spatially and temporally.

Spatial Aggregation

Using the mapping created in Step 1 and the filtered INRIX data from Step 2, the INRIX XD data was spatially aggregated on the CMP segments. In cases where multiple INRIX XD segments span a single CMP segment, the travel time was summed for all INRIX XD segments.

$$\text{CMP Travel Time} = XD_1 + XD_2 + \dots + XD_n$$

Temporal Aggregation

Temporal aggregation involved the translation of the CMP travel time metric for each five-minute of data into one average speed value corresponding to each CMP segment for the entire monitoring period. The following formula was used for this:

$$\text{Average CMP Speed} = \frac{\sum \text{CMP Length}}{\sum \text{CMP Travel time}}$$

Sample size information was retained to assess the confidence level in the computed statistics.

Sample Size

The sample size is the number of data points that contributed to the final calculation of average speed. The sample size varied on each INRIX XD segment through removal of data points during the filtering process and through the processes discussed below.

APPENDIX A

Removal of XD data points with scores of 10 and 20 (Step 2 above) eliminated data for particular five-minute time periods from one or more of the XDs that comprise certain CMP segments. The example shows a longer CMP segment which is comprised of four XDs. The table shows the data scores for each XD for each five-minute time period. In time periods 1, 2, and 7, one of the XDs had a data score of 20 and therefore the record from that XD was excluded for those minutes. In time period 6, two of the XDs had data scores of 20 and similarly, these XD records were also excluded for time period 6.

A check was performed to ensure that any time periods that had INRIX XD segments removed were not included in the analysis. Where INRIX XD data were available for less than 99% of the INRIX XD segments that were chosen for mapping, five-minute time period was removed. To extend the above example further, if XD1 was less than 1% of the CMP segment length, then it would still be possible to use the data in Time periods 1 and 2 (in addition to time periods 3, 4 and 5). This can be justified, because XD1 does not contribute significantly to the distance-based average speed calculation.

In a small minority of cases, using the 99% threshold resulted in removal of too many time periods and an inadequate sample size. In these cases, the threshold was lowered to 70% to ensure that the sample size was adequate. A minimum sample size of 50 was used.

Floating Car Survey Data

Once floating car survey data was collected using GPS units, it was processed to extract the average speed and travel time on subsegments of each CMP segment. The subsegment average speeds and travel times were then input into a spreadsheet that calculated aggregated average speed for each CMP segment using the segment's travel time and length.

A.3.2 | Assign LOS

The next step in the analysis process was to assign LOS based on the average speeds calculated for each CMP segment. As adopted in the 2013 CMP, LOS is estimated for the entire CMP network based on HCM 1985 with the exception of Tier 2 arterial segments, which were also reported using HCM 2000 for comparison purposes. This study uses the LOS speed standards as shown in **Tables A-1, A-2 and A-3**.

Table A-1: Freeway LOS (Source: HCM 1985)

Level of Service	Speed (mph)	Density (pc/mi./ln ¹)	V/C Ratio	Maximum Service Flow (pcphpl ²)
A	≥ 60	≤ 12	0.35	700
B	≥ 55	≤ 20	0.58	1,000

APPENDIX A

Assigning LOS - Freeways

Based on the average speed of the freeway in the morning and afternoon peak-periods and using the HCM standards as shown in **Table A-1**, LOS was estimated for each CMP segment in each time period.

Assigning LOS - Ramps and Special Segments

Based on the suggested guidelines from the HCM:

- LOS A occurs when vehicles are traveling at a free-flow speed for the given roadway conditions.
- LOS F occurs when speeds have dropped below 50 percent of the free-flow speeds.
- Levels of Service B to E are calculated at even intervals between free-flow speeds and LOS F speeds.

To determine LOS for these ramps, the free-flow speed was obtained from special studies conducted in 1992, during off-peak low-volume conditions. There is one ramp segment that is classified as a weaving segment and is therefore not assigned an LOS consistent with previous monitoring cycles. The performance of this segment can be judged on its average speed.

Assigning LOS - Arterials

Both HCM 1985 and 2000 methods first require classification of the arterial according to its free-flow speed and other road characteristics. The road classification based on HCM 1985 could be Class I, II or III and based on HCM 2000 it could be Class I, II, III or IV.

Using the classification of the street and the average travel speed, and based on relevant HCM standards as shown in **Tables A-2** and **A-3**, LOS for the arterial segment is determined for both HCM methodologies. For the number of LOS F segments being tallied and compared to previous years, LOS F segments were identified using the HCM 2000 methodology for Tier 2 Arterials.

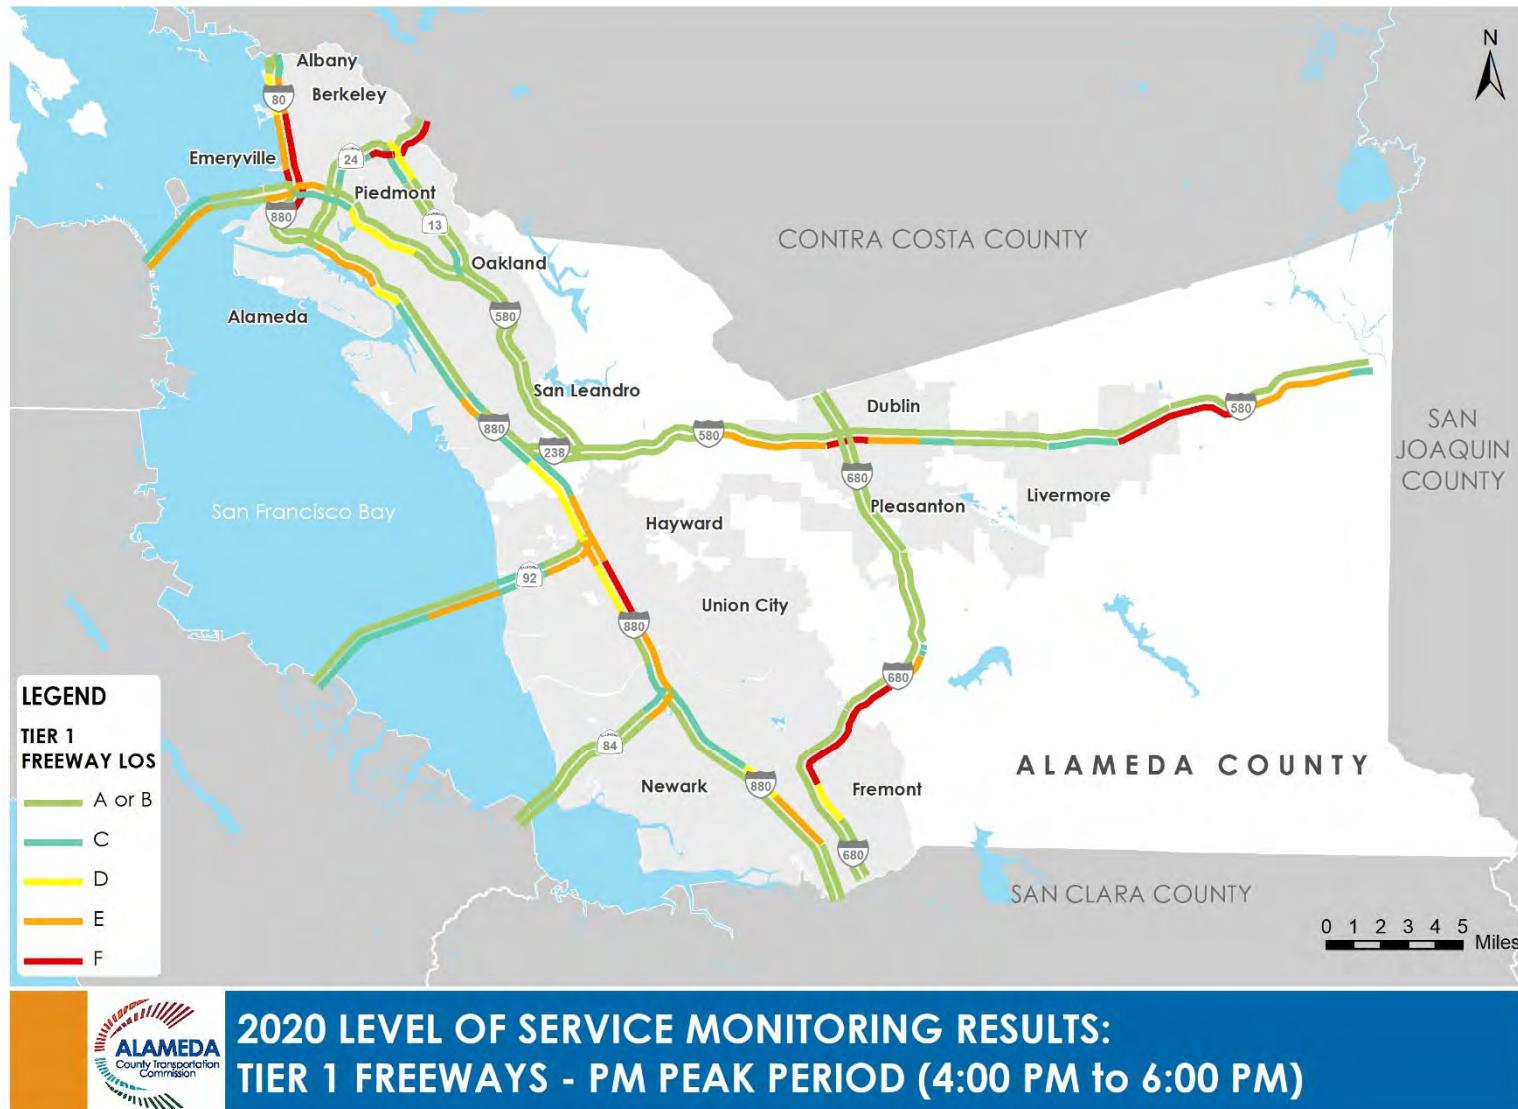

Assigning LOS - Rural Roadways

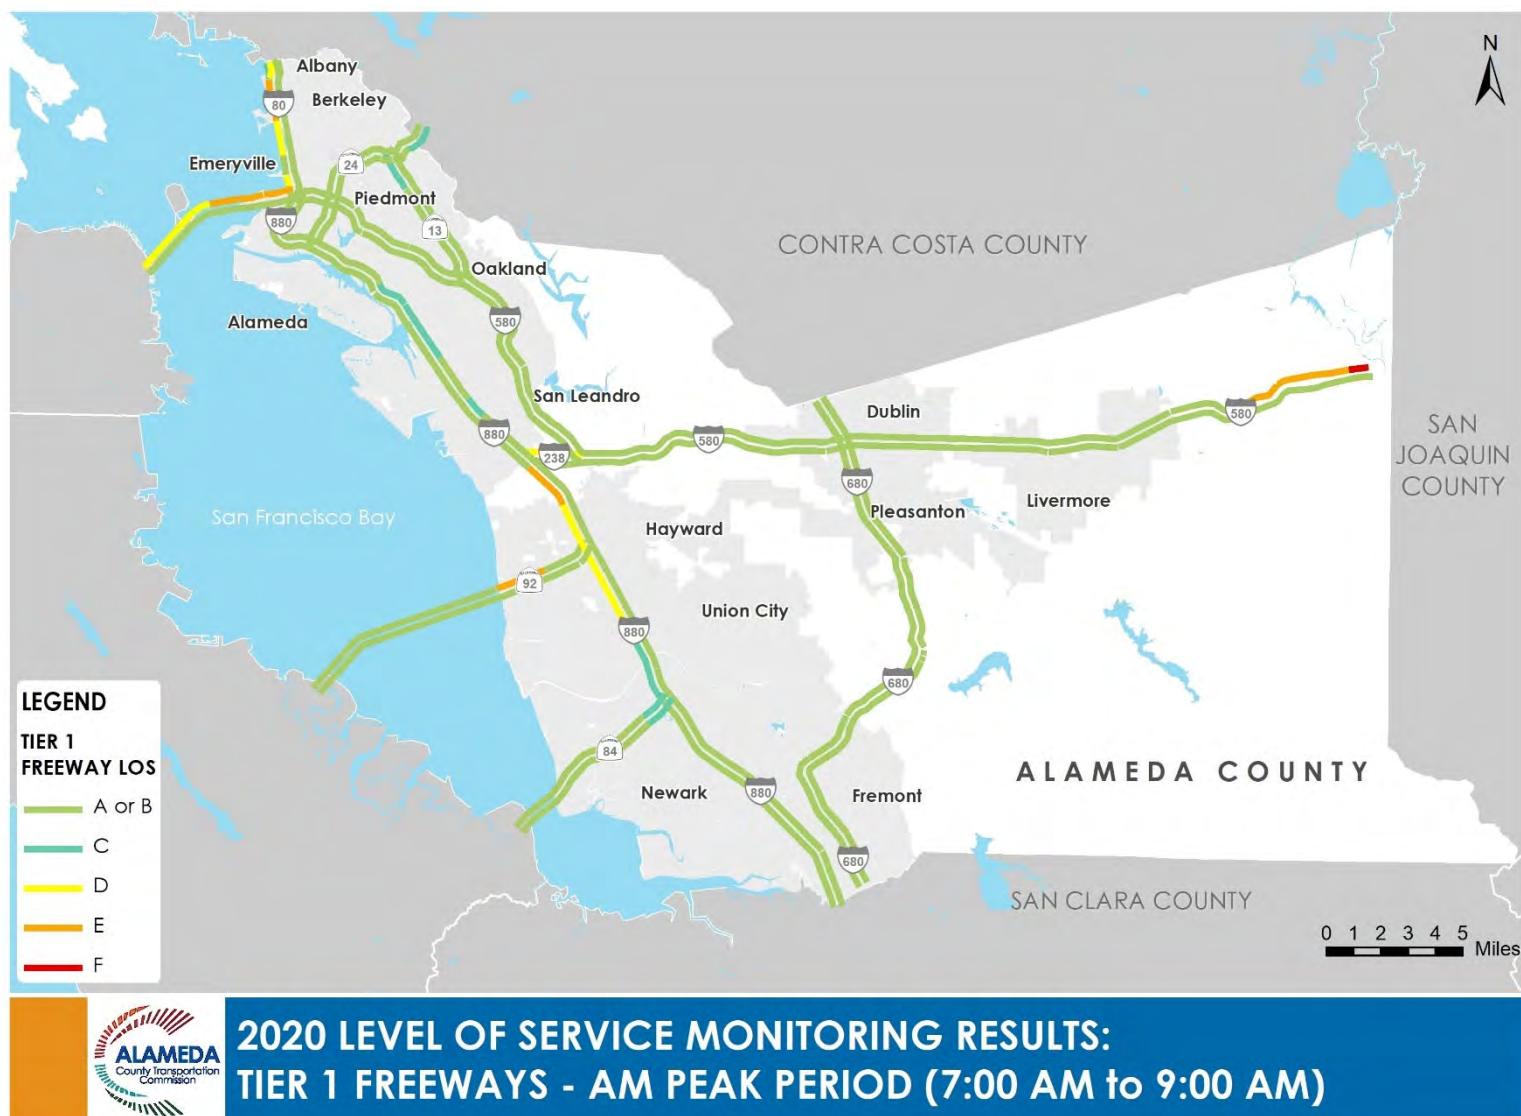

Several Tier 1 and Tier 2 CMP routes (mostly located in the east county) are rural roadways and require a special analysis procedure. Traffic and speed characteristics are fairly uniform on these roadways. Variations in speed are a function of roadway curvature and the presence of slower trucks in the traffic stream. One such Tier 1 roadway is SR-84 between the southern city limit of Livermore and Mission Boulevard in Fremont. Rural roadways identified in the Tier 2 network include a portion of Vasco Road in Livermore and a part of Crow Canyon Road, both connecting to the county line.

To be consistent with the methodology used in the prior monitoring cycle, based on guidelines from HCM 1985 LOS A occurs when vehicles are traveling near the free-flow speed for the given roadway conditions. LOS F occurs when speeds have dropped below 50 percent of the free-flow speeds. Levels of Service B to E are calculated at even intervals between free-flow speeds and LOS F speeds. This is adapted from the HCM 1985. Based on this methodology, LOS is calculated for rural roadways (both Tier 1 and Tier 2) for the current monitoring cycle.

Appendix D | Freeway Corridor Performance

Driving trips, especially commute trips, nearly always cover several CMP segments and commonly traverse multiple freeways. It is thus useful to aggregate the results for the entire corridor to understand changes in travel demand.

Corridor performance analysis was focused on seven freeway corridors within the County, separated by directions, as shown in Figure D-1. The east-west corridors include I-580 (between SR 238 and I-205) and SR 24, while majority of the corridors are in the north-south direction, including I-80, I-580 (between I-80 and I-238), I-680, I-880, and SR 13.

Average speeds on the freeway corridors were separated by directions. As shown in Figure D-1, average speeds in the afternoon peak period have remained relatively stable from 2010 to 2018, but increased in 2020 due to the COVID-19 pandemic. The increase in corridor average speeds ranged from 2 to 29 mph. The lowest speed occurred on I-80 in the EB direction, but average speed still increased by about 7 mph on this corridor in 2020.

Very low speeds (below 35 mph) were still seen in 2020 on the I-80 EB corridor and SR 24 EB corridor during the afternoon peak period, both of which have experienced very low speeds historically. In 2020, the average speeds still increased by about 7 mph on the I-80 EB corridor and 10 mph on the SR 24 EB corridor.

FREEWAY CORRIDOR PERFORMANCE

Figure D-1: Freeway Corridor Average Speeds (2010 – 2020) – PM Peak Period

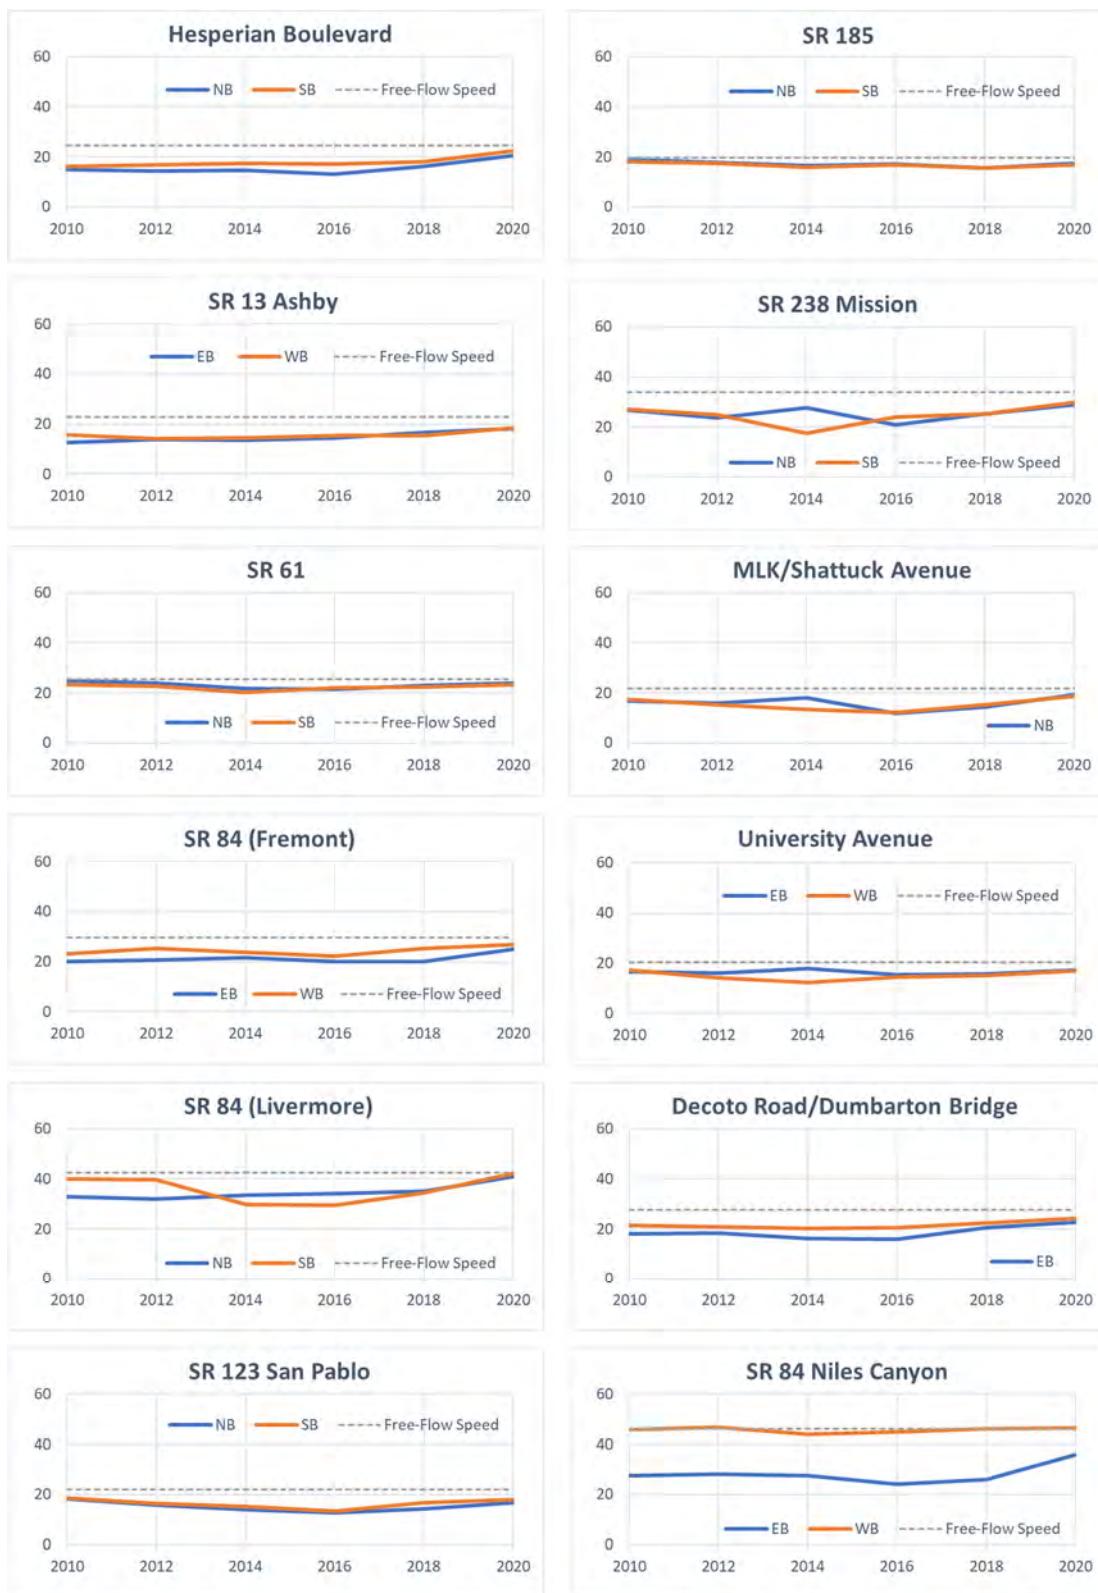

Appendix E | Arterial Corridor Performance

Corridor performance analysis was focused on 12 Tier 1 arterials within the County during the afternoon peak period, separated by directions, as shown in **Figure E-1**. Average speeds in the afternoon peak period have remained relatively stable from 2010 to 2018, but increased in 2020 due to the COVID-19 pandemic. The increase in corridor average speeds ranged from 1 to 10 mph. Corridors with the highest increase in average speeds were SR 84 Niles Canyon EB (+10 mph), SR 84 Livermore SB (+8 mph), SR 84 Livermore NB (+6 mph), and SR 238 Mission Boulevard SB (+5 mph). On the other hand, corridors with the lowest increase in average speeds included SR 13 Ashby EB (+1 mph), University Avenue EB (+1 mph), and SR 123 San Pablo Avenue SB (+1 mph). It seems that the corridors with speed increased the most were mostly located at suburban areas, while those with speed increased the least were mostly located in urban areas. In suburban areas, traffic signals are typically dispersed (i.e., lower traffic signal density) which makes it easier for speed increase when traffic demand is lower. However, in urban areas, traffic signals are typically closely-spaced and signal timings are more competitive among various users (e.g., crossing traffic, bicycles, pedestrians), which makes it harder for speed increase.

ARTERIAL CORRIDOR PERFORMANCE

Figure E-1: Tier 1 Arterial Corridor Average Speeds (2010 – 2020) - PM Peak Period

Appendix F | CMP Conformity

Tier 1 roadways that report LOS F conditions in the afternoon peak period are further analyzed for CMP conformity. As shown in **Table F-1**, only the Tier 1 CMP network in the afternoon peak period is subject to LOS conformance and associated deficiency planning (where applicable). All other monitoring and data collected are used for informational purposes only.

Table F-1: CMP Network Monitoring Periods and Purposes

Tier	Time Period	CMP Category	Purpose
Tier 1	PM	Freeways	
		Arterials	Legislative Conformity
		Special Segments	
Tier 1	Freeways		
	AM	Arterials	
		Ramps & Special Segments	
	Weekends	Freeways	Informational only
Tier 2	AM and PM	Arterials	
Other	AM and PM	HOV & Express Lanes	
		Transit	

Based on the analysis, if the roadway is identified to be deficient, state legislation requires the respective local jurisdiction to prepare a deficiency plan that details the cause of the deficiency, identifies measures to improve the performance of the roadway, and a funding plan for the proposed improvements. A roadway may be exempt from being identified as deficient for the following reasons:

- It operated at LOS F in the base monitoring year (1991 and 1992 when the CMP network was formed) and is therefore *grandfathered* in at LOS F;
- It is located within an Infill Opportunity Zone;
- Construction activities affected the normal flow of traffic;
- It carries a certain volume of interregional trips (analysis performed using the Alameda Countywide Travel Demand Model);
- It is impacted due to freeway ramp metering or recent traffic signal coordination;
- It operated at LOS F due to traffic generated by developments such as low-income housing, a high-density development, or a mixed-use development subject to certain criteria.

There were 20 Tier 1 segments operating at LOS F in 2020 in the afternoon peak period. Of these 20 segments, 18 were exempt from deficiency planning requirements because they were grandfathered as LOS F in the 1991-1992 LOS surveys. Alameda CTC's travel model was used to estimate interregional trips (one of several possible exemptions identified in state legislation) on the remaining two segments. After removing trips originating from outside Alameda County, LOS was estimated. Based on this analysis, no new deficient segments were identified.
